

FIG. 134.—Oblique section of a bronchus in an area of lobular pneumonia from which streptococcus hemolyticus was cultivated. The peribronchial tissues are infiltrated with pus, the mucosa is raised from its basement membrane by seropurulent exudate, and there is considerable pus in the narrowed lumen of the bronchus. The infection appears to have reached this bronchus by extension from without. Accession number 3107, Army Medical Museum. Negative number 45229. Hematoxylin and eosin stain; $\times 115$
