

FIG. 57.—Early stage of organization of the exudate in a pulmonary atrium. Reticulum is extending into alveolar exudate which contains relatively little fibrin. The fibers extend throughout the exudate and no apparent connection with cells can be seen. There is some regeneration of epithelium along the atrial wall. In the exudate are round and polygonal cells the exact character of which can not be determined except that there are a few lymphocytes. Accession number 3572, Army Medical Museum. Negative number 45488. Reticulum stain;  $\times 745$
