

FIG. 111.—Early stage of streptococcus lobular pneumonia. Exudate is largely serous; the alveolar walls are infiltrated with leucocytes, are edematous, and appear to have been the first involved. The epithelium is partially desquamated, such desquamation being more marked in the wall of alveoli, the lumen of which contains many leucocytes. Extension in this case appeared to be outward from the walls of terminal bronchioles. Accession number 3102, Army Medical Museum. Negative number 45283. Hematoxylin and eosin stain; $\times 140$
